# Sentiment Analysis

Sentiment analysis is a technique that involves analyzing a piece of text to determine its emotional tone, which could be positive, negative, or neutral. It is commonly performed various ML algorithms. It has a variety of applications in fields like social media monitoring, customer feedback analysis, and brand reputation management.

# Sentiment Analysis and Stock Price Variation

Fluctuations in a stock's price can be caused by several factors, one of which is sentiment. Sentiment is typically influenced by news related to the company, such as positive or negative earnings reports, product launches, missed targets, or the departure or death of a key figure. These events can affect the demand and price of shares in the stock market.

# The Objective

The main aim of this project is to demonstrate how the price of a stock fluctuates as a result of relevant human sentiment using Machine Learning algorithms. Also, we have performed the experiments with and without the preprocessing part for the textual data.

5 rows × 27 columns

Figure: Top 5 rows of the Dataset

# How the Dataset looks like

- Data ranges from 2008 to 2016 and the data from 2000 to 2008 was scrapped from Yahoo finance.
- There are 25 columns of top news headlines for each day in the data frame.
- Class 1- the stock price increased.
- Class 0- the stock price stayed the same or decreased.

- We have split the data set into **train** and **test** datasets.
- Apart from “a”to “b” and “A”to “B”, we have removed everything.
- We have also converted the sentences into lower case and then joined all of the sentences in a row together.
- Next we have removed the **stopwords** that is inbuilt in the **NLTK** library.
- Further on, we have performed **Lemmatization** on the data.

# Is the Dataset Balanced?

Here, we have plotted a pie chart to check if the dataset is balanced or not.

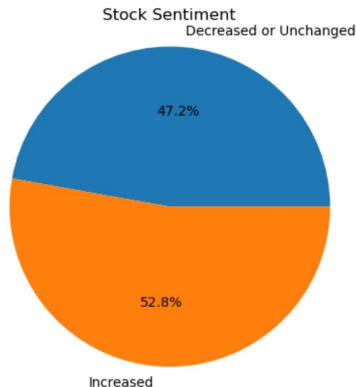

Figure: The Dataset is More or Less Balanced

# Output vs Negative Word Count

Here, we see how the outputs are distributed with regard to the number of negative word count in the corresponding input. We have used the builtin list of negative words from **NLTK**.

Figure: Output vs The Number of Negative Words

# The Sentiment Distribution

We have calculated the sentiment score of each of the headlines (without the preprocessing), using **SentimentIntensityAnalyzer()**, which we have imported from **nltk.sentiment.vader**. Here is the sentiment distribution

Figure: Sentiment Distribution of News Headlines using VaderSentiment

# Using Bag of Words

We have used **Bag of Words** in order to create the input vectors. After the application, After applying Bag of Words, we get a matrix representation of the corpus of text documents where each row corresponds to a document and each column corresponds to a word in the corpus. The matrix contains the frequency of occurrence of each word in the corresponding document.

- Converting the Textual Data into Vectors

## 3 Applying Random Forest

## 4 Applying Naïve Bayes

## 5 Applying Convolutional Neural Network

## 6 Conclusion

Random Forest is an ensemble learning method used for classification and regression. It uses **Bagging** and builds multiple decision trees using randomly selected features and samples, and aggregates their predictions to make a final prediction. The algorithm reduces overfitting, which is a problem with Decision Trees.

# The Experiment With Removing Stopwords and Lemmatization

The accuracy is 0.51 with the support of 378.

- 4 Applying Naïve Bayes
- 5 Applying Convolutional Neural Network
- 6 Conclusion

Naive Bayes is a probabilistic algorithm used for classification tasks in machine learning. It works by assuming that the presence or absence of a feature is independent of the presence or absence of any other feature, hence the name "naive". It calculates the probability of each class given a set of input features and selects the class with the highest probability as the output.

# The Experiment Without Removing Stopwords and Lemmatization

The accuracy is 0.85 with the support of 378.

# Convolutional Neural Network

Convolutional Neural Network (CNN) is a type of neural network used for image, audio and text analysis. It consists of input, convolution, activation, pooling, fully connected and output layers. The convolution layer applies filters to the input matrix to extract features, while pooling layers reduce dimensionality to avoid overfitting.

# The Experiment Without Removing Stopwords and Lemmatization

The accuracy is 0.82 with the support of 378.

# Comparing the Performances

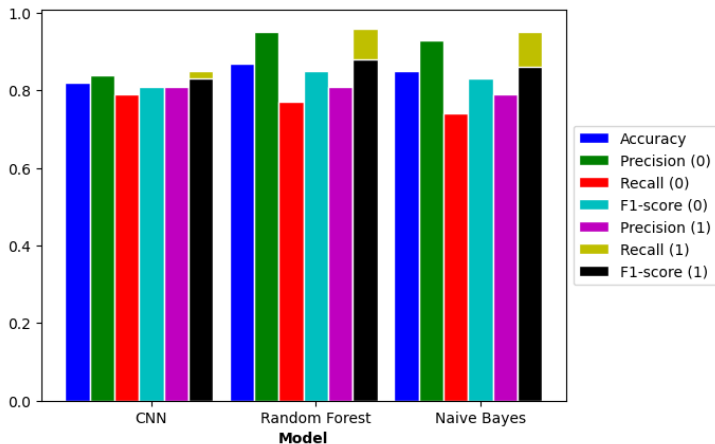

Figure: Comparing the Performances

# What We Learned?

- Standard textual data cleaning may not work for all sentiment analysis.
- Removing stopwords can delete relevant keywords, so one needs to be careful.
- Stemming/Lemmatization may mix words with different contexts and reduce accuracy.
- Naive Bayes, CNN, and Random Forest work well for text classification.
- In this use case, Random Forest > Naive Bayes > CNN in terms of performance.
